

5) Ball and Acme Screw Drive Mechanisms

This section will introduce most of the more common types of drive mechanisms found in linear motion machinery. Ideally, a drive system should not support any loads, with all the loads being handled by a bearing system. Topics discussed will include, but not be limited to, the mechanism of actuation, efficiency, accuracy, load transfer, speed, pitch, life cycle, application and maintenance. Each type of drive system will be accompanied by a diagram and useful equations when applicable. Some of the terms used with screws, the most common drive component, are as follows:

lead	— advance of the nut along the length of the screw per revolution
pitch	— distance between corresponding points on adjacent thread forms (pitch = lead / # of starts)
# of threads	— number of teeth found along a unit length of the screw (1 / pitch)
# of starts	— number of helical grooves cut into the length of the shaft
outer diameter	— largest diameter over the threaded section (at top of threads)
root diameter	— smallest diameter over the threaded section (at base of threads)
stub	— specific type of ACME thread where the root diameter is larger to provide for a more heavy-duty screw (the threads look “stubby”)
critical shaft speed	— operating speed of spinning shaft that produces severe vibrations during operation. This is a function of length, diameter, and end supports.
maximum compressive load	— maximum load that can be axially applied to the screw before buckling or permanent deformation is experienced. Also referred to as column strength.
end bearing supports	— the screw must be supported at one or both ends with thrust type bearings. Depending upon the application, it may also be desirable to provide for a stiffer system by incorporating angular contact bearings (fixed support).

Although shafts, gear trains, belt and pulley, rack and pinion, and chain and sprocket drives are practical in other applications, they require special consideration when used in CNC machinery. This is because there is typically backlash associated with these types of drives, which increases the system error. Thorough technical descriptions of these types of drives can be found in the Stock Drive Components Library.

Lead screws are threaded rods that are fitted with a nut. There are many types of threads used, but the most prevalent in industry is the ACME lead screw. Because the ACME thread is an industry standardized thread style, it is easily interchanged with parts from various manufacturers. The basic function of a screw is to convert rotary input motion to linear output motion. The nut is constrained from rotating with the screw, so as the screw is rotated the nut travels back and forth along the length of the shaft. The friction on the nut is a function of environment, lubrication, load, and duty cycle; therefore, practical life cycle is difficult to quantify.

Lead screw/nut drive systems are available in a variety of sizes and tolerances. Contact is primarily sliding, resulting in relatively low efficiency and a wear rate proportional to usage. **Advantages** include the self-locking capability in back drive mode which is good for vertical applications, low initial costs, near silent operation, manufacturing ease, and a wide choice of a materials. **Disadvantages** of ACME screws include lower efficiencies (typically 30-50%, depending on nut preload) which require larger motor drives, and unpredictable service life.

Ball Screws are very similar to lead screws with the exception of a ball bearing train riding between the screw and nut in a recirculating raceway. This raceway is generally lubricated, which allows for predictable service life. Due to the increased number of mating and moving parts, matching tolerances becomes more critical. The screw threads have rounded shapes to conform to the shape of the balls. The function, terminology, and formulas are the same as found with lead screws, however the performance of ball screws is far superior. The rolling action of the balls versus the sliding action of the ACME nut provides significant advantages. **Advantages** of ball screw drives are increased efficiency (typically up to 90 – 95%) which allows required motor torque to be lower, predictable service life, low wear rate and maintenance costs. **Disadvantages** include limited material choice, higher initial cost, and an auxiliary brake is required to prevent back driving with vertical applications.

Helpful Formulas: When determining the amount of input torque required to produce an amount of output linear force, there are many factors to consider. The following equations provide a practical approach in making force and torque calculations.

Force Calculations:

$$F_T = F_A + F_E + F_F \quad (1)$$

where: F_T = Total Force

F_A = Acceleration Force

F_E = External Force

F_F = Friction Force

$$F_A = \frac{W}{g} \cdot \frac{a}{12} \text{ lb} \quad (2)$$

where: W = total weight to accelerate (lb)

a = linear acceleration (in/sec²)

g = acceleration from gravity (ft/sec²)

External Force (F_E) may be due to gravity in vertical applications, or may be from external work requirements (feeding material, stretching material, etc.)

Friction Force (F_F) required to overcome all of the friction in the load bearing system (with a low friction bearing system, this can be negligible)

The Total force must be below the compressive (thrust) rating of the screw chosen. A modest factor of safety should be added to the total force so that unexpected dynamic loads are safely handled by the screw system.

Torque Calculations:

$$T = F_T \cdot \frac{L}{2\pi e} \quad (3)$$

where: F_T = Total Force (lbs)

L = Lead (inches)

e = efficiency (no units, use 0.9 for Ball screws assemblies.)

Technical Information

Total Force = 100 lbs (3)
 Lead = 0.20 inches
 Efficiency = 0.9 (Ball screw)

$$T = \frac{100 \text{ lbs} \times 0.20 \text{ inches}}{2 \pi (0.9)} = 3.54 \text{ lb-inches}$$

Total Force = 25 lbs (3)
 Lead = 0.10 inches
 Efficiency = 49%

$$T = \frac{25 \text{ lbs} \times 0.10 \text{ inches}}{2 \pi (.49)} = 0.81 \text{ lb-inches}$$

The Torque required should be well below the torque rating of the motor chosen. A modest factor of safety should be added to the torque required so that unexpected dynamic loads are safely handled by the driving system.

Selecting and Sizing Screw Drive Systems: When choosing a particular screw for a given application, there are several factors to be considered. Required rpm, critical speed and maximum compressive strength are the most important design features that determine screw design parameters, and can be calculated according to the following equations. Since thread style design is irrelevant in these calculations, the same equations and charts can be used for both lead screws and ball screws. Bearing configuration must be considered when using these equations. The following diagrams represent the typical bearing end support arrangements.

A. Fixed-Free

B. Simple-Simple

C. Fixed-Simple

D. Fixed-Fixed

$$\text{rpm} = \frac{\text{linear velocity (in/min)}}{\text{lead (in/rev)}} \quad (4)$$

Maximum Speed:

$$C_s = F(4.76 \times 10^6) \frac{d}{L^2} \quad (5)$$

where:

C_s = critical speed (rpm)
 d = root diameter of screw (inches)
 L = length between supports (inches)
 F = end support factor (see diagram)
 case A.: 0.36
 case B.: 1.00
 case C.: 1.47
 case D.: 2.23

Maximum Load

$$P = F(14.03 \times 10^6) \frac{d^4}{L^2} \quad (6)$$

where:

P = maximum load (lbs) (critical load)
 d = root diameter of screw (inches)
 L = maximum distance between nut and load carrying bearing
 F = end support factor (see diagram)
 case A.: 0.25
 case B.: 1.00
 case C.: 2.00
 case D.: 4.00

The formulas above can be represented graphically by the charts on following pages. These charts have been compiled for screws made of stainless steel. Speeds, loads, diameters, bearing arrangements and products are referenced. It must be realized that a screw may be able to rotate at very high rpm's, but the nut may have more strict limitations. For this reason, we have truncated the ball screw rpm diagrams to a top end of 4000 rpm, and provided each type screw with their own charts. Please note that the ball screw charts are only represented for screws of 16 mm and 25 mm diameters.

Technical Information

TRAVEL RATE VS. LENGTH FOR STANDARD ACME SCREWS

CRITICAL SPEED

TRAVEL RATE
IN INCHES PER MINUTE

TRAVEL RATE IN INCHES / MIN.

PURPOSE

This graph was designed to simplify the selection of the proper lead screw so as to avoid lengths and speeds which will result in vibration of the assembly (critical speed). The factors which can be controlled after a particular maximum length is determined are: method of bearing support and choice of lead screw diameter.

USE OF THE GRAPH

1. Choose preferred bearing support means, based on design considerations.
2. On the proper bearing support horizontal line (A, B, C or D) choose length of lead screw.
3. Draw vertical line at the lead screw length, determined at (2.), and draw a horizontal line at the travel rate.
4. All sizes to the right and above the intersection point in (3.) are suitable for this application.
5. Screw sizes are coded as follows:

ONE END FIXED OTHER END FREE	REF A	6	12	18	24	30	36	42	INCHES
BOTH ENDS SUPPORTED	REF B	10	20	30	40	50	60	70	INCHES
ONE END FIXED OTHER END SUPPORTED	REF C	12	24	36	48	61	73	85	INCHES
BOTH ENDS FIXED	REF D	15	30	45	60	75	90	105	INCHES

LENGTH

MAXIMUM LENGTH (IN.) ADJUSTED FOR BEARING SUPPORT "Y" DIMENSION

Ball & Acme Screw Assembly Life Expectancy

SPECIFICATIONS

Pitch	Screw Dia.	Axial Load (N)	
		Dynamic (C _a)	Static
2.5	16	3500	5500
4	16	2600	4200
5	6	4600	7200
5	25	5100	12600
10	16	4200	6500
10	25	5100	12600
20	16	1900	2500
20	25	3570	8800

16 mm LIFE EXPECTANCY

$$L = \left[\frac{C_a}{F_m} \right]^3 \times 10^6$$

L = life expectancy expressed in number of revolutions

C_a = dynamic load rating (N) [for acme nuts, see design load column on catalog pages].

F_m = average axial load (N).

Example: For 10 mm pitch screw, 16 mm dia., C_a = 4200 N carrying an average axial load, F_m = 200 N (45 lbs.) the expected life is:

$$L = \left| \frac{4200}{200} \right|^3 \times 10^6 = 9.261 \times 10^9 \text{ revolutions.}$$

At an average of 1000 rpm this will result in:

$$\frac{9.261 \times 10^9 \text{ revolutions}}{1000 \text{ rpm}} \times \frac{1 \text{ hour}}{60 \text{ minutes}} = 154 \text{ 000 hours}$$

of expected operational life. Note that the nature of the motion (jerky, smooth, etc.) will affect the life expectancy.

25 mm LIFE EXPECTANCY

Lead Screw Formulas and Sample Calculations

Linear Speed (ipm)

$$\text{Linear Speed} = \frac{\text{steps / second}}{\text{steps / revolution}} \times 60 \times \frac{1}{p}$$

where:

p = lead screw pitch in threads per inch

Axial Force (lb)

$$\text{Force} = \frac{2\pi}{16} \times T \times p \times \text{eff.}$$

where:

T = torque (oz·in)

p = lead screw pitch in threads per inch

eff. = efficiency expressed as a decimal: 90% = 0.90

Note: Ball screws are generally 85% to 95% efficient. Acme lead screw efficiency is generally 35% to 45%, but can be as high as 85%.

A. Calculating the torque required to accelerate a mass moving horizontally and driven by a ball bearing lead screw and nut. The total torque the motor must provide includes the torque required to:

- accelerate the weight
- accelerate the lead screw
- accelerate the motor rotor
- overcome the frictional force

To calculate the rotational equivalent of weight w :

$$I_{(eq)} = w \times \frac{1}{p^2} \times \left(\frac{1}{2\pi}\right)^2$$

where:

w = weight (lb)

p = pitch (threads per inch)

$I_{(eq)}$ = equivalent polar inertia (lb·in²)

to calculate lead screw inertia (steel screw)

$$I (\text{screw}) = D^4 \times \text{length} \times .028$$

Example:

Weight = 1000 lb

Velocity = 0.15 feet per second

Time to Reach Velocity = 0.1 seconds

Ball Screw Diameter = 1.5"

Ball Screw Length = 48"

Ball Screw Pitch = 5 threads per inch

Motor Rotor Inertia = 2.5 lb·in²

Friction Force to Slide Weight = 6 oz

$$I(\text{eq}) = w \times \frac{1}{p^2} \times .025 = 1000 \times \frac{1}{25} \times .025 = 1.0 \text{ lb} \cdot \text{in}^2$$

$$I(\text{screw}) = D^4 \times \text{length} \times .028 = 5.06 \times 48 \times .028 = 6.8 \text{ lb} \cdot \text{in}^2$$

$$I(\text{rotor}) = 2.5 \text{ lb} \cdot \text{in}^2$$

$$I(\text{total}) = 10.3 \text{ lb} \cdot \text{in}^2$$

Velocity is 0.15 feet per second, which is equal to 1800 steps per second (motor steps in 1.8° increments).

Torque to accelerate system:

$$T = 2 \times I_o \times \frac{\omega}{t} \times \frac{\pi \times 1.8}{180} \times \frac{1}{24} = 2 \times 10.3 \times \frac{1800}{0.1} \times \frac{3.1416 \times 1.8}{180} \times \frac{1}{24} = 484 \text{ oz} \cdot \text{in}$$

Torque to overcome friction:

$$F = .393 \times T \times p \times \text{eff.}$$

$$T = \frac{F}{.393 \times p \times \text{eff.}} = \frac{\frac{6}{16}}{.393 \times 5 \times 0.90} = 0.22 \text{ oz} \cdot \text{in}$$

where:

F = frictional force (lb)

T = torque (oz·in)

p = lead screw pitch (threads per inch)

Total torque required = 0.22 oz·in + 484.00 oz·in = 484.22 oz·in

After determining the required motor size, it is recommended to add a 20% factor of safety so that unexpected dynamic loads are easily handled by the motor.

Sizing Servo Motors: Two separate torque figures are needed when selecting a DC motor — a peak torque, being the sum of acceleration and friction torques, and a continuous torque, which is the friction component only. The torque produced by the motor is given by:

$$T = K_T I$$

where K_T is the motor torque constant (e.g., Nm/amp) and I is the drive current (amp). The choice of motor and drive must satisfy the following conditions:

1. The product of K_T and peak drive current must give the required peak torque
2. The product of K_T and continuous drive current must produce sufficient continuous torque.
3. The maximum allowable motor current must be greater than the peak drive current.
4. At maximum speed and peak current, the voltage developed across the motor must be less than 80% of the drive supply voltage.

The voltage across the motor is given by:

$$E = K_E \omega + R I$$

where K_E is the motor voltage constant, ω the speed, R the winding resistance (ohms) and I the peak current (amperes). The speed units should be the same in each case; i.e., if the voltage constant is in volts per radian per second, then ω should also be in radians per second.

To make the most efficient use of the drive, the chosen solution should utilize most of the peak drive current

and most of the available voltage. Motor manufacturers usually offer alternative windings, and care should be taken to select the most appropriate.

Example:

Leadscrew Length: 80 in

Leadscrew Diameter: 1.5 in

Leadscrew Pitch: 2.54 in

Table Weight: 1000 lb

Linear Table Speed Required: 472 inches/min

Acceleration Time: 120 ms

Inertia of Leadscrew: $J = \frac{D^4 L}{36} = 11.25 \text{ lb}\cdot\text{in}^2$

Inertia of Table: $J = \frac{W}{40 p^2} = 3.88 \text{ lb}\cdot\text{in}^2$

Total inertia = 15.13 lb·in²

Maximum Speed = 472"/min = 1200 rpm (equivalent to 4000 full steps/sec)

Acceleration Torque:

$$T = \frac{J \alpha}{764t} = 660 \text{ oz}\cdot\text{in} \text{ (4.65 N}\cdot\text{m)}$$

This takes no account of motor inertia, so a suitable motor will be capable of producing around 1000 oz·in torque.

Again, as with stepper selection, it is recommended to add a 20% factor of safety so that unexpected dynamic loads are easily handled by the motor.
